2.2 Controls

A detailed view of the “Controller” subsystem is shown in Fig. 3. The “Peak Current Controller” component is responsible for current regulation. The “Mode_select” subsystem allows the user to choose between different control modes for the RGB LED module. The B-G474E-DPOW1 Discovery kit’s joystick inputs are read as digital input signals that are used to start and stop mode cycling, set the global brightness level, and enable the PWM outputs. Four signal LEDs are used as indicators displaying the mode of operation.

Figure 3: Controller subsystem

Peak current controller

In a peak current-mode controller, at the beginning of each switching cycle the output is set (gate signal is turned ON) without a pre-determined duty cycle. Then, when the sensed inductor current exceeds the peak current reference value, the output is reset (gate signal is turned OFF). The duty cycle is therefore determined by the rise of the inductor current during the on-time.

One of the drawbacks of the peak current-mode controller is that it suffers from an inherent instability if the applied PWM duty cycle is greater than 50%. This is explained in Fig. 4. If a small disturbance is introduced into the system and if the applied duty cycle is less than 50%, the disturbance eventually decays to zero. However, if the applied duty cycle is greater than 50%, the inductor current will start to diverge and will no longer be stable. The resulting duty cycle values will vary from small to large, on an

alternating cycle basis, called sub-harmonic oscillations. To limit these sub-harmonic oscillations, instead of providing a constant peak current reference, additional slope compensation is applied, as shown in Fig. 4. This ensures the stability of the inductor current [3][4].

Figure 4: Slope compensation

Brightness and color control

The project is configured so that both brightness and color are independently controllable.

The global brightness function of each LED is performed at constant current, using peak current-mode control. For a given color mix, dimming is achieved by burst mode operation, where pulses of peak current are alternated with periods of zero current (by turning the MOSFET OFF), as shown in Fig. 5. To prevent any flickering effect that the human eye may detect, the burst mode frequency is set to 400 Hz. The LED brightness is adjusted proportionally to the peak current period relative to the zero current period.

The color mixing is defined by the peak current threshold for each LED. For the RGB output to be red, the current of the red LED will be at a maximum and all other LED currents will be zero. The RGB output will be different shades when the current thresholds of each LED are at different values. For example, a purple color will be visible with equal red and blue LED peak current threshold, and zero current in the green LED.

The PWM generation and peak current-mode control is handled by the Peak Current Controller (PCC) block of the STM32 target library. The high-resolution timer (HRTIM) of the peak current controller is set to generate a PWM frequency of 250 kHz. Refer to Section 2.2 for a detailed description of the PCC operation.

Peak current reference (*ipeak_ref*) is provided as an input to the PCC block. The peak current reference is a function of two parameters, the burst duty ratio (*Bd*) and the peak current threshold (*ipeak_threshold*). The duty ratio (*Bd*) of the peak current reference defines the global brightness of all LEDs and is modulated at 400 Hz, the burst mode frequency. The higher the duty ratio, the brighter the LED. The peak current threshold (*ipeak_threshold*) specifies the peak current and relative brightness for each LED.

Figure 5: LED peak current-mode control with burst operation

Operating modes

In this model, the LED can be driven in three modes. The user can switch between the modes as seen in Fig. 6.

- RGB LED mode: This mode scans the entire color spectrum.
- White LED mode: This mode scans the entire white-brightness range. The same RGB LED is used, but red, green and blue colors are mixed to obtain white.
- Constant duty mode: In this mode the RGB LED delivers constant color and brightness.

RGB LED mode

The control logic for RGB LED mode is shown in Fig. 7. This mode scans the entire RGB color spectrum, by independently adjusting the current threshold (*i_{peak_threshold}*) of the peak current reference for each of the red, blue and green LEDs, as shown in Fig. 8. A triangular RGB pattern, is set as the current threshold, where only two LEDs are enabled at a time. To generate this triangular pattern in PLECS, a state machine block is used. The RGB spectrum scan also includes logic to pause or resume the color spectrum scan.

The global brightness, which is set by the duty ratio (*Bd*) of the peak current reference, remains constant at any time. However, there is an option to manually increase or decrease the global brightness of the LED, using the up and down buttons on the joystick. This will change the applied burst mode duty cycle of the Peak Current Controller block.

White LED mode

The control logic for white LED mode is shown in Fig. 9. This mode corresponds to an automatic dimming of the entire white brightness range. All three RGB LEDs are simultaneously enabled to obtain a white color. In this mode, the duty ratio (*Bd*) of the peak current reference is adjusted using a triangular

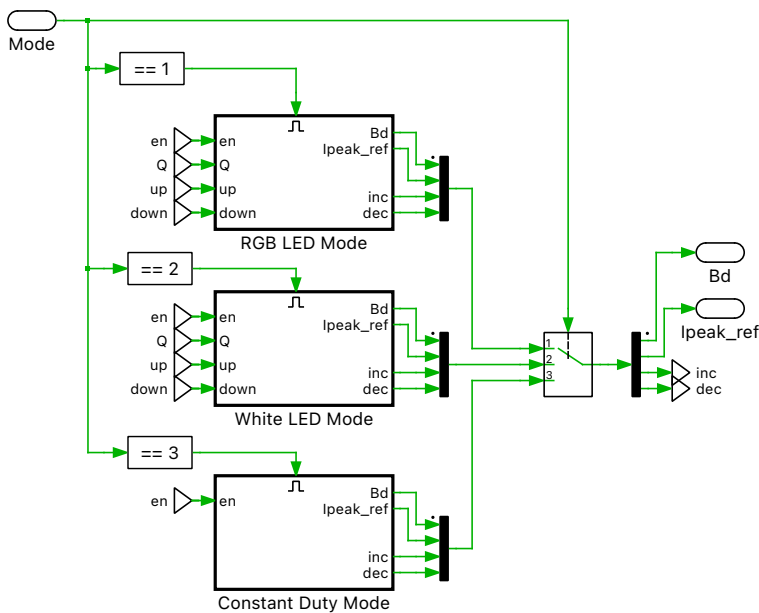

Figure 6: Mode Select

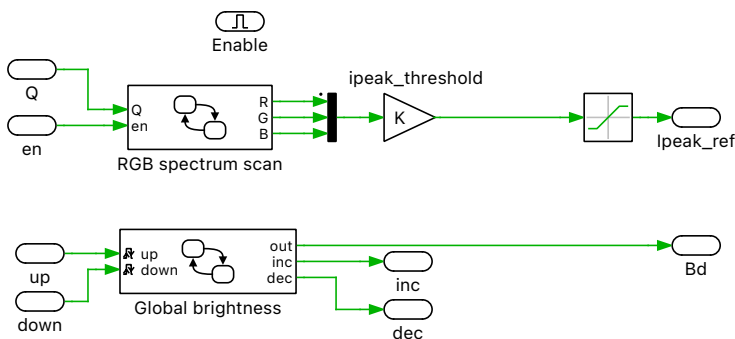

Figure 7: Control logic for RGB LED mode

Figure 8: *ipeak_threshold* R, G, B pattern for color spectrum scan [1]

wave for a pulsating change in brightness. All the three LEDs are enabled using the same Bd , as shown in Fig. 10.

At low brightness levels, with Bd values below 0.25, the current threshold (*ipeak_threshold*) value is adjusted as well. This allows lower amounts of global light energy during the start of the LED ON sequence, thereby dimming the LED much more efficiently. For higher brightness, with Bd values above 0.25, the *ipeak_threshold* is set at the maximum value.

Similar to the RGB LED mode, the white mode also includes logic to automatically pause or resume the white brightness spectrum scan, and to increase or decrease the global brightness of the LED, using the

Multi-tasking code

The PLECS Coder and the STM32 Target Support Package allow the user to generate multi-tasking code for the STM32 family of MCUs. Multi-tasking code unlocks processing power for controls regulating multiple system outputs with dynamics on a range of time-scales. In this model multi-tasking code is used since joystick and LED tasks can be executed at a slower rate, compared to the peak current controller.

Multi-tasking code generation is configured in the **Scheduling** tab of the **Coder + Coder options...** dialog. By changing the **Tasking mode** to multi-tasking and the **Task configuration** to specify, the

sample time for each task can be configured. The base sample time is always equal to the **Discretization step size**. The **Sample time** setting for lower priority tasks must be an integer multiple of the base sample time. Up to 15 slower lower priority tasks that execute at different rates can be specified, preserving processor time for the fastest, highest priority task in the application. For further information, refer to the "Code Generation" section in the PLECS User Manual [5].

Blocks in the PLECS schematic are assigned to lower priority tasks using the Task library component. In this model two lower priority tasks are defined in addition to the Base Task, as seen in Fig. 3. The table below lists the sample times of the lower priority tasks, with respect to the Base Task. The execution rate of the Base Task (f_c), in this case is 20 kHz.

Task name	Sample time
Base Task	$1/f_c$
Joystick Task	$20/f_c$
LED Task	$1000/f_c$

3 Simulation

Offline simulation

Run the model as provided to observe the LED and inductor currents, as well as the PWM waveforms. If desired, the mode can be changed from the input labeled *Mode* of the subsystem labeled *Mode_select* in Fig. 3. The LED current waveform of the red LED, with a constant Bd of 0.1, is shown in Fig. 14. The offline model also allows the user to emulate pushing joystick buttons.

Note that the offline simulation may not reveal changing waveforms, as the RGB color scanning and white LED mode brightness operates with long periods on the order of tens of seconds.

Figure 14: Current through the red LED with a constant Bd of 0.1

Embedded target operation

In addition to running a simulation of this demo model in offline mode on a computer, the "Controller" subsystem can be directly converted into target specific code for the STM32G474RE board.

Follow the instructions below to upload the "Controller" subsystem to a STM32 MCU.

- 1 Connect the MCU to the host computer through a USB cable.

- 2** From the **System** tab of the **Coder + Coder options...** window, select “Controller”.
- 3** Next, from the **Target** tab, select STM32G4x from the dropdown menu. Then under the **General + Chip** sub-tab, select G474RE.
- 4** To deploy the MCU target directly from PLECS, uncheck the `Generate code only` parameter, choose the desired **Programming interface** from the dropdown menu. The default programming interface is OpenOCD.
- 5** Then click **Build**.

Note If programmed correctly, the green LED labeled *LD4_green* should blink.

For advanced users who are familiar with STM32CubeIDE, there is an option to `Generate code only`. Locate the appropriate `cg` folder from the template project (refer to [6] for step-by-step instructions), enter its path into the **STM32CubeIDE project directory** field and click **Build**. The code of the “Controller” subsystem will be automatically generated. Then, proceed to build and debug the project as a normal STM32CubeIDE project.

Note In order to enable PWM signals, push the center button of the joystick. When the PWM signals are enabled, the green LED labeled *LD4_green* turns solid ON.

The RGB LED should now scan the entire RGB color spectrum. It is possible to pause/resume automatic scanning by pressing the left/right joystick keys respectively. When automatic scanning is paused, the orange LED labeled *LD3_orange* should turn ON and when the scanning is resumed again, the LED turns OFF.

To increase/decrease the global RGB LED brightness, press the up/down joystick keys respectively. When increasing the global brightness, the red LED labeled *LD5_red* should turn ON. Then *LD5_red* should start to blink as soon as the brightness upper limit is reached. Similarly, when decreasing the global brightness the blue LED labeled *LD2_blue* should turn ON and when the global brightness lower limit is reached, *LD2_blue* should start blinking.

To switch the mode from RGB LED mode to white LED mode, follow the instructions below to connect to the external mode of the STM32 MCU.

- 1** From the **System** menu on the left hand side of the **Coder + Coder options...** window, select “Controller”.
- 2** Next, from the **External Mode** tab, select the appropriate **Target device** and click **Connect**. The default communication link of the model is set to `Serial over GDB`, and the device name configured to `127.0.0.1`.
- 3** Optionally, **Activate autotriggering** to observe the test results in the “Controller” subsystem Scope.
- 4** Then, return to the “Controller” schematic, and set the input labeled *Mode* to the subsystem labeled *Mode_select* in Fig. 3 to 2.

Similar to the RGB LED mode, it is possible to pause/resume automatic scanning or increase/decrease the global brightness of the LED in the white LED mode as well.

4 Conclusion

This model demonstrates the high-brightness RGB LED control application as defined in the application note AN5345 from STMicroelectronics, using the B-G474E-DPOW1 Discovery kit.
